

## MATH CLUB: INVERSION

SEPTEMBER 24, 2017

### INVERSION

**Definition.** Let  $S$  be a circle with center at  $O$  and radius  $r$ . *Inversion* in circle  $S$  is the transformation  $I$  of the plane that sends every point  $P$  to a point  $P'$  such that

- $P'$  is on the ray  $OP$
- $OP \cdot OP' = r^2$

Note that  $I(O)$  is undefined.

Inversion is not a rigid motion — it doesn't preserve distances. Yet, it has a number of interesting properties summarized below.

**Theorem 1.** Let  $I$  be an inversion in circle  $S$ , with center at  $O$  and radius  $r$ . Then

1.  $I$  sends every straight line not containing  $O$  to a circle through  $O$ . Conversely, it sends every circle through  $O$  to a straight line.
2.  $I$  sends every circle not containing  $O$  to another circle.

Note that while  $I$  sends circles to circles, it doesn't send center of a circle to the center of transformed circle.

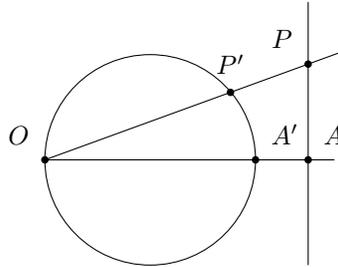

**Theorem 2.** Let  $I$  be an inversion. Then  $I$  preserves angles: if two lines  $l, m$  intersect at point  $P$  at angle  $\alpha$ , then  $I(l), I(m)$  will intersect at point  $I(P)$  at angle  $\alpha$ , and similar if one or both lines is replaced by a circle.

(By definition angle between two circles at intersection point  $P$  is the angle between their tangent lines at  $P$ .)

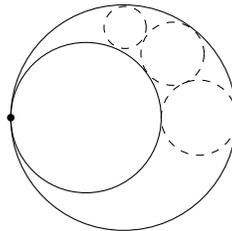

If two circles  $C_1, C_2$  go through  $O$  and are tangent to each other at  $O$ , then  $I(C_1), I(C_2)$  are two parallel lines. Conversely, if  $l, m$  are two parallel lines which do not go through  $O$ , then  $I(l), I(m)$  are two circles that are tangent at point  $O$ .

SOME PROBLEMS

1. Given two non-intersecting circles  $C_1, C_2$  and a point  $P$  (outside of both circles), construct a circle through  $P$  which is tangent to both  $S_1, S_2$ .
2. Given three circles  $C_1, C_2, C_3$  such that  $C_1$  and  $C_2$  are externally tangent to each other and  $C_3$  is outside  $C_1, C_2$ , can you construct the fourth circle  $C$  tangent to  $C_1, C_2, C_3$ ? [Hint: use inversion!]
3. Prove Theorem 1.1. [Hint: use similar triangles to show that in the figure below  $OA \cdot OA' = OP \cdot OP'$ .]

4. (a) Let  $C$  be a circle, and let  $O$  be a point outside the circle. Let  $l$  be a line through  $O$  which intersects circle  $C$  at points  $P, P'$ . Prove that then  $OP \cdot OP' = r^2$ , where  $r$  is the length of the tangent from  $O$  to circle  $C$ .  
 (b) In the notation of part (a), show that in this case, inversion in circle with center at  $O$  and radius  $r$  sends circle  $C$  to itself.  
 (c) Prove Theorem 1.2.
5. Let two circles  $S_1, S_2$  be tangent to each other, with one circle inside the other, as shown in the figure below. Construct a sequence of circles  $C_1, C_2, \dots$ , which are tangent to both  $S_1, S_2$ , and each next one is tangent to the previous (three first such circles are shown in the figure below by dashed lines). Prove that then centers of all circles  $C_i$  lie on some circle.

6. And now for something completely different... (and simple!)  
 You have a collection of numbers  $1, 2, \dots, 25$  written on the board. Every minute Daniil chooses a pair of numbers, erases them, and writes a new number instead: if the numbers were  $a, b$ , then he replaces them with  $a + b + ab$ . He repeats this until there is a single number written on the board.  
 What is this number?
