Heat

Traditionally, Heat was measured in calories (cal):

• 1 calorie is an amount of heat needed to increase the temperature of 1g of water by 1°C.

• For nutritional/dietary purposes people use "big Calories" (Cal, with capital "C"). **1 Cal=1000cal (or simply kilocalorie). By definition, this is an amount of heat needed to increase the temperature of 1 kg (1 liter) of water by 1°C.**

• Heat is a form or energy, so calories can be converted to Joules:

1cal=4.184J 1Cal=1000cal=4184J(used for dietary purposes)

Homework

Problem 1

How much energy, in Joules, do you consume with each standard serving of your favorite food (check the nutrition label)? Assuming that you need about 70,000 J to run 1 mile, what distance can you run on one serving?

Problem 2

A droplet of water falls from the height h=1000m, onto a thermally isolating surface. Assume that all mechanical energy goes to heating the water. Find the change in its temperature ΔT .
