What is Matter?

1. Common "classical" definition (known as *mechanical, abstract mathematical*), René Descartes, Isaac Newton - 17th century:

"Matter is anything that has mass and takes up space"

- 2. Late 19th century definition (based on physical and chemical structure):
 - "Matter is made up of atoms"

This *atomic*, or <u>ordinary</u>, matter is in turn made up of interacting *subatomic particles* — usually a nucleus of protons and neutrons, and a cloud of orbiting electrons.

THERE ARE MORE ATOMS IN A SINGLE GRAIN OF SAND THAN GRAINS OF SAND ON EARTH.

Atoms are very small!

Voyage into the World of Atoms: https://www.youtube.com/watch?v=7WhRJV_bAie

Snowflake ~1-3 mm

Ice crystal unit cell 5 nm

A typical snowflake is made of about 10¹⁸-10¹⁹ atoms.

Brownian Motion Robert Brown, 1827

 In 1827, while looking through a microscope at particles found in pollen grains in water, Brown noted that the particles moved through the water but was not able to determine the mechanisms that caused this motion.

- <u>Albert Einstein, 1905</u>: Any minute particle suspended in a liquid (or gas) moves chaotically under the action of collisions with surrounding atoms and molecules. The intensity of this chaotic motion is increased with an increase in temperature.
- This explanation of Brownian motion served as **definitive confirmation** that **atoms and molecules actually exist**.

Study of Matter

- Physics physical science that studies forms of matter, its change and motion through space-time, and related concepts such as energy and force.
- Chemistry physical science that studies material substances, their composition and change of composition (chemical reactions), as well as matter behavior related to chemical reactions.

Physical science - branch of natural science that studies non-living systems. **Natural science** major branch of science, that tries to explain and predict nature's phenomena, based on empirical evidence.

Science - systematic effort of acquiring knowledge-through observation and experimentation coupled with logic and reasoning.

Everyday Properties of Matter

We can <u>observe</u> the following about <u>ordinary matter</u>:

Ρ

R

Ο

Ρ

Ε

R

Ε

S

- How it **looks** (Shiny, Dull, Color, etc.)
- How it feels (Hard, Soft, Rough, Smooth, etc.)
- How it smells (Sweet, Sharp, Terrible, No Smell, etc.)
- How it **sounds** (Loud, Soft, Echo, No Sound, etc.)
- What it does (Stretch, Break, Magnetize, Ignite etc.)

Anything else?

How it moves
 How it changes

States of Matter

- <u>Matter</u> can exist in several different *forms*, or *states* of aggregation.
- Matter commonly exists in <u>four</u> <u>fundamental</u> <u>states</u>:

≻Solid
≻Liquid
≻Gas
≻Plasma

 The different states of matter are based upon distance between particles (atoms and/or molecules), particle <u>arrangement</u>, and <u>energy</u> of particles.

SOLIDS

- Particles of <u>solids</u> are tightly packed.
- The intramolecular forces between particles are strong: the particles cannot move freely but <u>can only</u> <u>vibrate about a fixed position</u>.
- Solids have a stable, definite shape and a definite volume.
- Solids can only change their shape by force, as when broken or cut.

LIQUIDS

- Particles of <u>liquids</u> are tightly packed but are far enough apart to slide over one another (*mobile structure*).
- The shape of a liquid is not definite but is determined by its container.
- Liquids are known to be *nearly incompressible*. At constant temperature and pressure, liquids have a definite volume.
- The volume of liquid is usually greater than the volume of the corresponding solid (the best-known *exception* being *water*).

- Particles of a <u>gas</u> are very <u>far apart</u> and <u>move freely</u>.
- A gas has an indefinite shape and an indefinite volume: it will expand to *fill the entire container* in which it is confined.
- A gas is *compressible*.
