

Chemistry - 1

Let's continue the journey - day 2

What are the building blocks and the building rules?

- What is the difference between different atoms?
- Why do the atoms connect the way they connect and not in some different way?
- Why did the atoms of oxygen and nitrogen connect by two and argon stay alone in the air?
- Can the carbon dioxide atoms be connected differently?
- How do atoms attach to each other?

$$a_{n+1} - a_n = 0_n$$

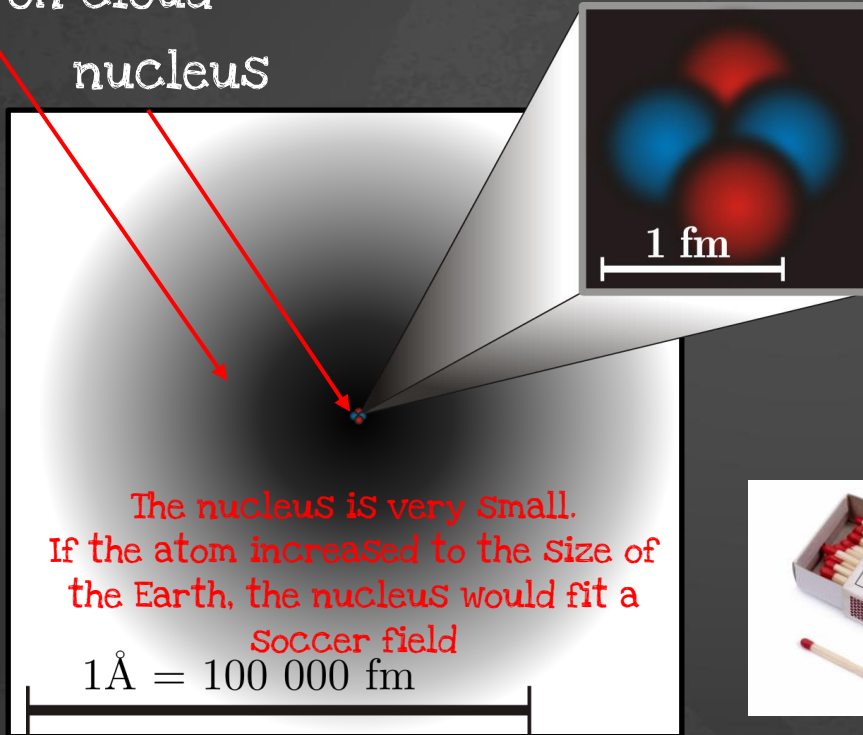

Atomic composition

- Atoms are made up of even smaller particles, which define properties of elements
- If you change the arrangement of these particles or the number of these particles you will change the properties of the element or the element itself

Electron cloud

nucleus

The nucleus is very small.
If the atom increased to the size of
the Earth, the nucleus would fit a

Soccer field

$$1 \text{ \AA} = 100\,000 \text{ fm}$$

- Almost all atomic mass is in the nucleus
- The density of matter in the nucleus is enormous - 10^{13} - 10^{14} g/cm^3 (density of lead is 11.29 g/cm^3)
- The atoms are tiny, classical physics cannot accurately predict their behavior (quantum effects)

2.5×10^9 tons ~ 200
Egyptian pyramids

Atomic composition

- Atoms are made of nucleus and an electron cloud around it
 - The electron cloud has a negative charge, protons in the nucleus have positive charge.
- In each atom the number of protons is equal to the number of electrons so as a whole an atom is neutral
 - (An atom can loose or acquire electrons, getting charged)
 - In addition to protons a nucleus contains neutrons. The neutrons do not have any charge
 - Electrons, protons and neutrons are subatomic particles

The size of the atom

If we shrink a million times..

A human hair is now thirty stories
thick..

Bacteria are the size of torpedoes..

And atoms are just barely visible as
tiny specks.

Shrink another thousand times
brings us to NANOMETER (10^{-9} meter)
scale. The little man is about 2 nm
tall, and the atoms are about $1/10^{\text{th}}$ of
his size

Let's shrink 10 more times to atomic size - 10^{-10} meter and look at a single carbon atom. Some electrons are humming around... but where are positive charges?

Now the man is a hundred times smaller, PICOMETER scale. That is a million of a millionth, or 10^{-12} actual size.

If the diameter of the atom were the length of a football field, then the nucleus would be smaller than a pea.

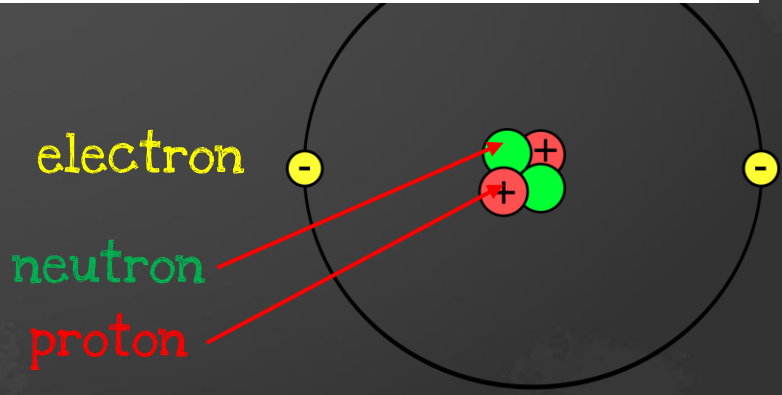

The atom is mostly empty space!

This is hydrogen atom

Atomic Number
Symbol
Name
Chemical Group Block

Atoms

The nucleus is held together by a powerful short-range force attraction called THE STRONG FORCE, which overcomes electrical repulsion.

This intense pull makes most nuclei virtually indestructible.

Atomic mass

- **Atomic number** – is the number of protons in nucleus
 - Atomic number of C?
- **Atomic mass ?** Each proton and neutron has 1840 times the mass of an electron

Particle	Mass	
	kg	AMU
PROTON	$1.673 \times 10^{-24} \text{g}$	1.00728
NEUTRON	$1.675 \times 10^{-24} \text{g}$	1.00867
ELECTRON	$0.00091 \times 10^{-24} \text{g}$	0.000549

- Chemists define an atomic mass unit, or AMU, to be precisely one-twelfth the mass of a ^{12}C atom. The common carbon atom has a mass of exactly 12.000000 AMU, by definition.
- All other atomic masses are computed relative to this reference.

Isotopes

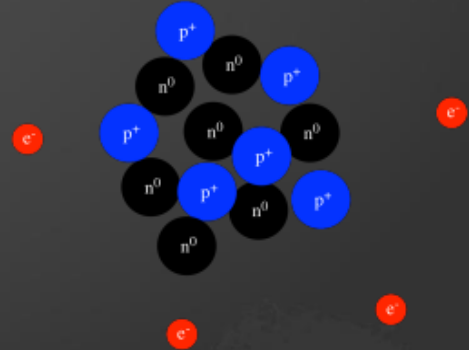

We can write it as ^{12}C

This atom has
6 protons
6 neutrons
6 electrons

This is carbon ("C") atom
It has :
6 protons
6 neutrons
6 electrons

It is still a carbon atom
We can write it as ^{13}C
In the natural carbon it is
present at ~1%

6 electrons

6 electrons

6 protons and
6 neutrons

6 protons and
7 neutrons

Atomic mass of C =
 $(0.989 \times 12) + (0.011 \times 13) = 12.011$

$$\text{atomic mass of an element} = \left(\begin{array}{l} \text{fractional} \\ \text{abundance of} \\ \text{isotope 1} \end{array} \times \begin{array}{l} \text{mass of} \\ \text{isotope 1} \end{array} \right) + \left(\begin{array}{l} \text{fractional} \\ \text{abundance of} \\ \text{isotope 2} \end{array} \times \begin{array}{l} \text{mass of} \\ \text{isotope 2} \end{array} \right) + \dots$$

Isotopes

Isotope - each of two or more forms of element that contain equal number of protons but different number of neutrons in their nuclei, and hence differ in relative atomic mass but no in chemical properties.

Most natural isotopes are stable
The unstable ones fall apart releasing subatomic particles and electromagnetic waves. This is called radioactivity

Element	Latin name	Atomic mass of the element in nature	Atomic mass of isotopes	% of isotope in the element in nature
Hydrogen ${}^1_1\text{H}$ ${}^2_1\text{H}$ (D)	Hydrogenium	1.0079	1.0078 2.0140	99.984 0.0156
Carbon ${}^{12}_6\text{C}$ ${}^{13}_6\text{C}$	Carboneum	12.011	12.000 13.00335	98.892 1.108
Nitrogen ${}^{14}_7\text{N}$ ${}^{15}_7\text{N}$	Nitrogenium	14.0067	14.00307 15.00011	99.635 0.365
Oxygen ${}^{16}_8\text{O}$ ${}^{17}_8\text{O}$ ${}^{18}_8\text{O}$	Oxygenium	15.9994	15.99491 16.9991 17.9992	99.759 0.037 0.204
Sodium ${}^{23}_{11}\text{Na}$	Natrium	22.9898	22.9898	100
Chlorine ${}^{35}_{17}\text{Cl}$ ${}^{37}_{17}\text{Cl}$	Chlorium	35.453	34.96885 36.9658	75.53 24.47

A Special element Hydrogenium

- Hydrogen is the only element that has different symbols and names for its isotopes:
 - ^1H - protonium
 - ^2D - deuterium
 - ^3T - tritium
