

## HW5

We can describe enthalpy as  $H = U + PV$ , where  $U$  – internal energy of the system,  $P$  – pressure of the system,  $V$  – volume of the system. Since we don't know the absolute value of  $U$  for our “chemical” purposes this equation is useless. But we can presume that our system is under constant pressure (pressure does not change), that is true for the most chemical reactions, and then we can calculate the enthalpy change (it is basically heat added or taken out from the system, system in our case is chemical reaction)

What substance is more stable, graphite or diamond?

In the reaction with graphite 1 mole of  $\text{CO}_2$  is produced and 393.8 kJ of energy is released in the surrounding. In the reaction with diamond 1 mole of  $\text{CO}_2$  is produced and 395.7 kJ of energy is released. We can presume that diamond has higher energy compared to graphite, so diamond is less stable.

Enthalpy change ( $\Delta H$ ) of the reaction – amount of chemical heat energy taken in (giving out) in a reaction. If we know the sign of enthalpy change we can describe if a reaction is endothermic or exothermic.

Bond enthalpy: energy required to break 1 mole of a bond.

Let's break C – H bond (ignore all the other bonds that carbon has to have). We need energy to break this bond.

dot here represents electron, since bond is pair of electrons, when we break the bond, each atom is going to have unpaired electron now.

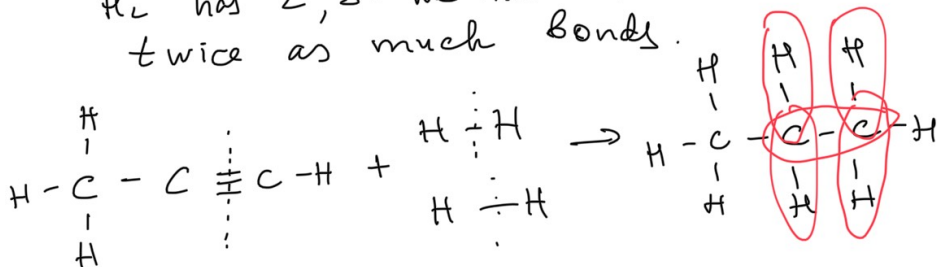

We will apply 413 kJ of energy to break this bond.

Information about different bond energies (bond enthalpy) can be found in tables online or in textbook. Bond enthalpies can be used to calculate enthalpy change ( $\Delta H$ ) of the reaction.

Let's look at the following problem: We need to find the enthalpy change of the reaction only knowing the bond energy of the reactants ( $\text{C}_3\text{H}_4$  and  $\text{H}_2$ ) and the product ( $\text{C}_3\text{H}_8$ ).

remember about coefficient  
H<sub>2</sub> has 2, so we have to break  
twice as much bonds.

We have to break .

one C≡C bond, bond enthalpy 835 kJ/mol  
and two H-H bond, bond enthalpy 436

5 bonds will be formed:

one C-C, bond enthalpy 346  
four C-H, 413 kJ/mol

To calculate  $\Delta H$  of the reaction

we have to subtract energy  
of the new bonds from the energy  
of the old bonds

$\Delta H_r = \text{energy of the broken bonds} -$   
 $\text{energy of the formed bonds}$

$$845 + (2 \cdot 436) - (346 + 4 \cdot 413) =$$

$$= -291 \quad \Delta H_r = -291 \text{ kJ/mol}$$

Let's look at the previous home work. Calculate enthalpy change for the following reaction

The enthalpy change for these reactions are known

Handwritten solution for calculating the enthalpy change of the target reaction:

- $2\text{C} + \text{O}_2 \rightarrow 2\text{CO} \quad \Delta H = -222 \text{ kJ/mol}$
- $\text{C} + \text{O}_2 \rightarrow \underline{\text{CO}_2} \quad -394$

Target reaction:  $2\text{CO} + \text{O}_2 \rightarrow \underline{\underline{2\text{CO}_2}}$

---

Reaction 1:  $2\text{C} + 2\text{O}_2 \rightarrow 2\text{CO}_2 \quad -788$

Reaction 2:  $2\text{C} + \text{O}_2 \rightarrow 2\text{CO} \quad -222$

Subtracting reaction 2 from reaction 1:

$$\begin{array}{r} 2\text{C} + 2\text{O}_2 \rightarrow 2\text{CO}_2 \\ - (2\text{C} + \text{O}_2 \rightarrow 2\text{CO}) \\ \hline \text{O}_2 \rightarrow 2\text{CO}_2 - 2\text{CO} \end{array}$$

Final reaction:  $2\text{CO} + \text{O}_2 \rightarrow 2\text{CO}_2$

Enthalpy change:  $-788 - (-222) = -566 \text{ kJ/mol}$

Diagram illustrating the Hess's Law cycle:

- Start:  $2\text{C} + \text{O}_2 + \text{O}_2$
- Path 1:  $2\text{C} + \text{O}_2 \rightarrow 2\text{CO} \quad -222$
- Path 2:  $2\text{C} + 2\text{O}_2 \rightarrow 2\text{CO}_2 \quad -394 \times 2$
- End:  $2\text{CO}_2$

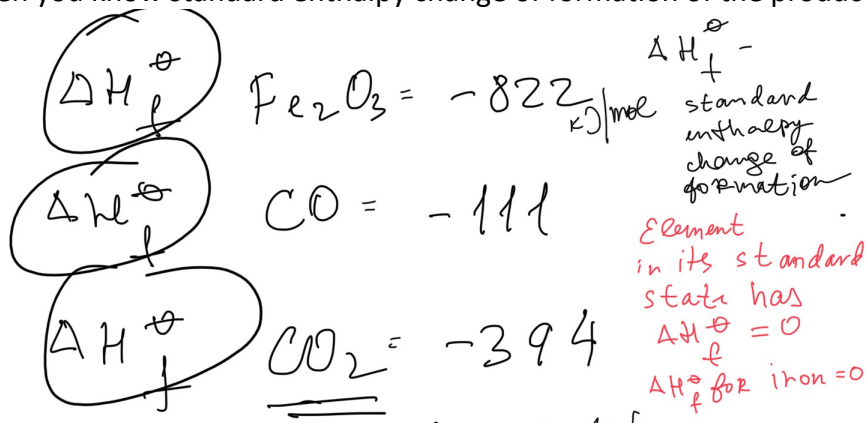

Final enthalpy change:  $-566$

Note: We multiply by 2 because we want to form 2 CO<sub>2</sub> molecules.

Multiply reaction number 2 by 2, because we need to count 2 CO<sub>2</sub> in the final reaction.

Subtract reaction 2 from reaction 1 including enthalpy changes, we will get our final reaction and the enthalpy change.

Calculate enthalpy change for the reaction  $\text{Fe}_2\text{O}_3 + 3\text{CO} \rightarrow 2\text{Fe} + 3\text{CO}_2$   
 When you know standard enthalpy change of formation of the products and reactants.

Knowing  $\Delta H_f^\ominus$  for the above substances calculate enthalpy change for the following reaction:  $\text{Fe}_2\text{O}_3 + 3\text{CO} \rightarrow 2\text{Fe} + 3\text{CO}_2$

symbol for sum  $\Sigma$   
 $\Delta H_r = \Sigma \Delta H_f^\ominus (\text{products}) - \Sigma \Delta H_f^\ominus (\text{reactants})$

our products 2 Fe and 3  $\text{CO}_2$   
 $2 \times 0 + 3 \times (-394)$

our reactants  $\text{Fe}_2\text{O}_3$  and 3 CO  
 $-822 + (3 \times -111)$

$\Delta H_r = 3 \times (-394) - (-822 + (3 \times -111)) =$   
 $= -27 \text{ kJ/mol}$

## Questions:

1. Calculate the enthalpy change for the reaction

We know that

2. Calculate the enthalpy change for the reaction

We know that

3. Calculate the enthalpy change for the reaction

Standard enthalpy change of formation for  $\text{NH}_3\text{(g)} = -46 \text{ kJ/mol}$ , for  $\text{NO (g)}$

$= 90 \text{ kJ/mol}$ , for  $\text{H}_2\text{O (g)} = -242 \text{ kJ/mol}$
