

Acceleration

- **Acceleration:**

$$a = \frac{\text{change in velocity}}{\text{time}} = \frac{\Delta v}{t}$$

Standard units of acceleration : m/s^2
(meters per second per second)

The formula for acceleration can be inverted to find the time:

$$t = \frac{\Delta v}{a}$$

Or the change in speed:

$$\Delta v = a t$$

Homework 6

Problem 1.

The largest passenger airplane, Airbus A380, needs 40 seconds to reach its takeoff speed, $v = 280$ km/h. What is the acceleration of the plane? Convert your answer to m/s^2 .

Problem 2.

If in the future humans are to reach the nearby stars, they would need spaceships traveling with speed close to the speed of light. Imagine that a spaceship is accelerating with acceleration 10 m/s^2 .

- a) How long would it take such a ship to reach $1/10$ of the speed of light? Speed of light is $3 \times 10^8 \text{ m/s}$.
- b) How long would it take such a ship to reach the Alpha Centauri system which is about 4 lightyears away from the Earth (and is the star system closest to us)? Assume that after reaching $1/10$ of the speed of light the spaceship continues to move with that speed.
