

**MATH 8**  
**ASSIGNMENT 27: EULER FUNCTION**  
MAY 10, 2026

**Theorem** (Fermat's Little theorem). *For any prime  $p$  and any number  $a$  not divisible by  $p$ , we have  $a^{p-1} - 1$  is divisible by  $p$ , i.e.*

$$a^{p-1} \equiv 1 \pmod{p}.$$

This shows that remainders of  $a^k \pmod{p}$  will be repeating periodically with period  $p - 1$  (or smaller).

A similar statement holds for remainders modulo  $n$ , where  $n$  is not a prime. However, in this case  $p - 1$  must be replaced by a more complicated number: the Euler function of  $n$ .

**Definition.** For any positive integer  $n$ , Euler's function  $\varphi(n)$  is defined by

$$\varphi(n) = \text{number of integers } a, 1 \leq a \leq n - 1, \text{ which are relatively prime with } n$$

Note that by previously proved results, "relatively prime with  $n$ " is equivalent to "is invertible mod  $n$ ".

For example, if  $n = p$  is prime, then any non-zero remainder mod  $n$  is relatively prime with  $n$ , so in this case  $\varphi(p) = p - 1$ . Some properties of Euler's function are given in problems below.

**Theorem** (Euler's theorem). *For any integer  $n > 1$  and any number  $a$  which is relatively prime with  $n$ , we have  $a^{\varphi(n)} - 1$  is divisible by  $n$ , i.e.*

$$a^{\varphi(n)} \equiv 1 \pmod{n}.$$

In the example when  $n = p$  is prime, we get  $\varphi(p) = p - 1$ , so in this case Euler's theorem becomes Fermat's little theorem.

For example,  $\varphi(10) = 4$ . This means that for any number  $a$  which is relatively prime with 10, remainders of  $a^k \pmod{10}$  (i.e., the last digit of  $a^k$ ) repeat periodically with period 4.

1. Prove that if  $a + b + c$  is divisible by 7, then  $a^7 + b^7 + c^7$  is also divisible by 7.
2. Compute  $\varphi(25)$ ;  $\varphi(125)$ ;  $\varphi(100)$ .
3. Let  $p$  be prime. Compute  $\varphi(p)$ ;  $\varphi(p^2)$ ;  $\varphi(p^k)$
- \*4. Use Chinese remainder theorem to show that if  $m, n$  are relatively prime, then a number  $a$  is invertible modulo  $mn$  if and only if it is invertible mod  $m$  and invertible mod  $n$ . Deduce from this that
$$\varphi(mn) = \varphi(m)\varphi(n) \quad \text{if } \gcd(m, n) = 1$$
5. Use the previous two problems to give a general formula for Euler's function: if  $n = p_1^{k_1} p_2^{k_2} \dots p_l^{k_l}$ , where  $p_i$  are distinct prime numbers, then  $\varphi(n) = ?$
6. Find  $5^{2092} \pmod{11}$ . What about the same number, but modulo  $11^2$ ?
7. Find the last two digits of  $14^{14^{14}}$ .
8. Find at least one  $n$  such that  $2013^n$  ends in 001 (i.e. the rightmost three digits of  $2013^n$  are 001). Can you find the smallest such  $n$ ?
9. Find the last three digits of  $7^{1000}$ . [Hint: first find what it is mod  $2^3$  and mod  $5^3$ .]

10. (a) Show that if  $a$  is not divisible by 7 or 11, then  $a^{60} \equiv a \pmod{77}$   
(b) Show that for any  $a$ , we have  $a^{61} \equiv a^{121} \equiv \dots \equiv a \pmod{77}$   
(c) Given a number  $a$  between 1 and 77, Alice computes  $b = a^{13} \pmod{77}$  and shows the answer to Bob. Show that then Bob can find  $a$  by using  $a = b^d$  for some  $d$ . [Hint: it suffices to find  $d$  such that  $13d \equiv 1 \pmod{60}$ ]
