

Which of the following objects...

1

2

3

4

5

6

- ...have the **same** volume?
- ...have the **same** density?
- ...have **different** mass?
- ...have **different** volume?
- ...have the **same** mass?
- ...have **different** density?

(note: all “atoms” here are the same;
all objects have the same thickness)

Charge, + or -, is the basic property of matter that gives rise to all **electrical** and **magnetic** forces and interactions.

- In atoms, **electrons** carry the **negative (-)** charge, and **protons** carry the **positive (+)** charge; neutrons have **NO (zero)** charge.
- SI unit of charge is **Coulomb**.
- The charge of a single electron, known as **elementary charge**, is equal to **negative 1.602×10^{-19} C**.
- The charge of a single proton is the same but **positive**.
- Matter is usually **charge-neutral**, meaning the positive and negative charges balance out.

Electromagnetism

is an interaction that occurs between particles that have electric charge

$$\text{ELECTRIC FORCE} = k \cdot \frac{\text{CHARGE} \cdot \text{charge}}{(\text{DISTANCE})^2}$$

$8.99 \cdot 10^9 \text{ N} \cdot \text{m}^2/\text{C}^2$

“electrostatic force constant”

A “strong” force at the atomic level... responsible for binding atoms into molecules and molecules into liquids and solids!

Like charges repel each other

Opposite charges attract each other

States of Matter

- Matter can exist in several different *forms*, or *states of aggregation*.
- Matter commonly exists in four fundamental states:

- Solid
- Liquid
- Gas
- Plasma

- The different states of matter are based upon distance between particles (atoms and/or molecules), particle arrangement, and energy of particles.

SOLID

- Particles of solids are **tightly packed**.
- The forces (*electromagnetic!*) between particles are strong: the particles cannot move freely but can only vibrate about a fixed position.
- Solids have a stable, **definite shape** and a **definite volume**.
- Solids can only change their shape *by force*, as when broken or cut.

LIQUID

- Particles of liquids are **tightly packed but are far enough apart to slide over one another (mobile structure)**.
- The **shape** of a liquid is **not definite** but is determined by its container.
- Liquids are known to be ***nearly incompressible***. At constant temperature and pressure, liquids have a **definite volume**.
- The **volume of liquid** is usually greater than the volume of the corresponding solid (the best-known **exception** being **water**).

GAS

- Particles of a gas are very far apart and move freely.
- A gas has an **indefinite shape** and an **indefinite volume**: it will expand to *fill the entire container* in which it is confined.
 - A gas is **compressible**.

A Comparison: The Three States of Matter

Solid

Liquid

Gas

Example: ICE → WATER → WATER VAPOR
