

Rainbows...in your backyard!

All you need is small **water droplets** and bright **sunlight!**

Rainbow...

**...how
to
make
it?**

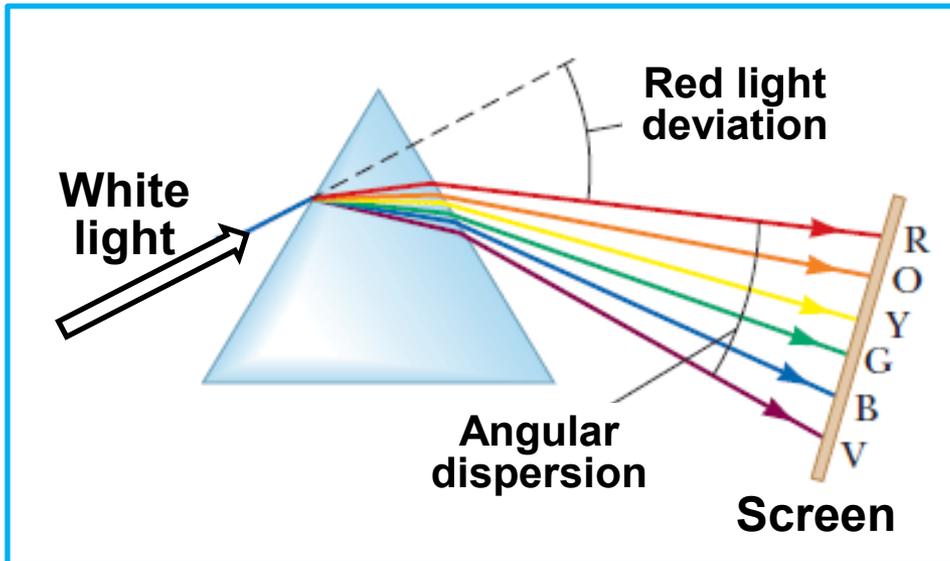

Dispersion of Light

splitting of light into its component colors

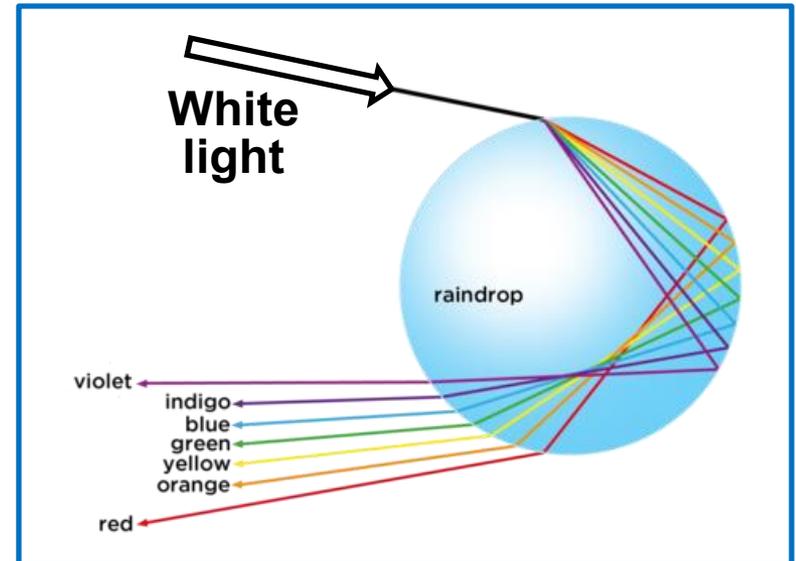

Different colors (wavelengths) of light *travel at different speed in the same material* and therefore refract differently:

- **Red** (longer wavelength) is **bent less**.
- **Violet** (shorter wavelength) is **bent more**.
- This allows for separation of colors in certain geometries.

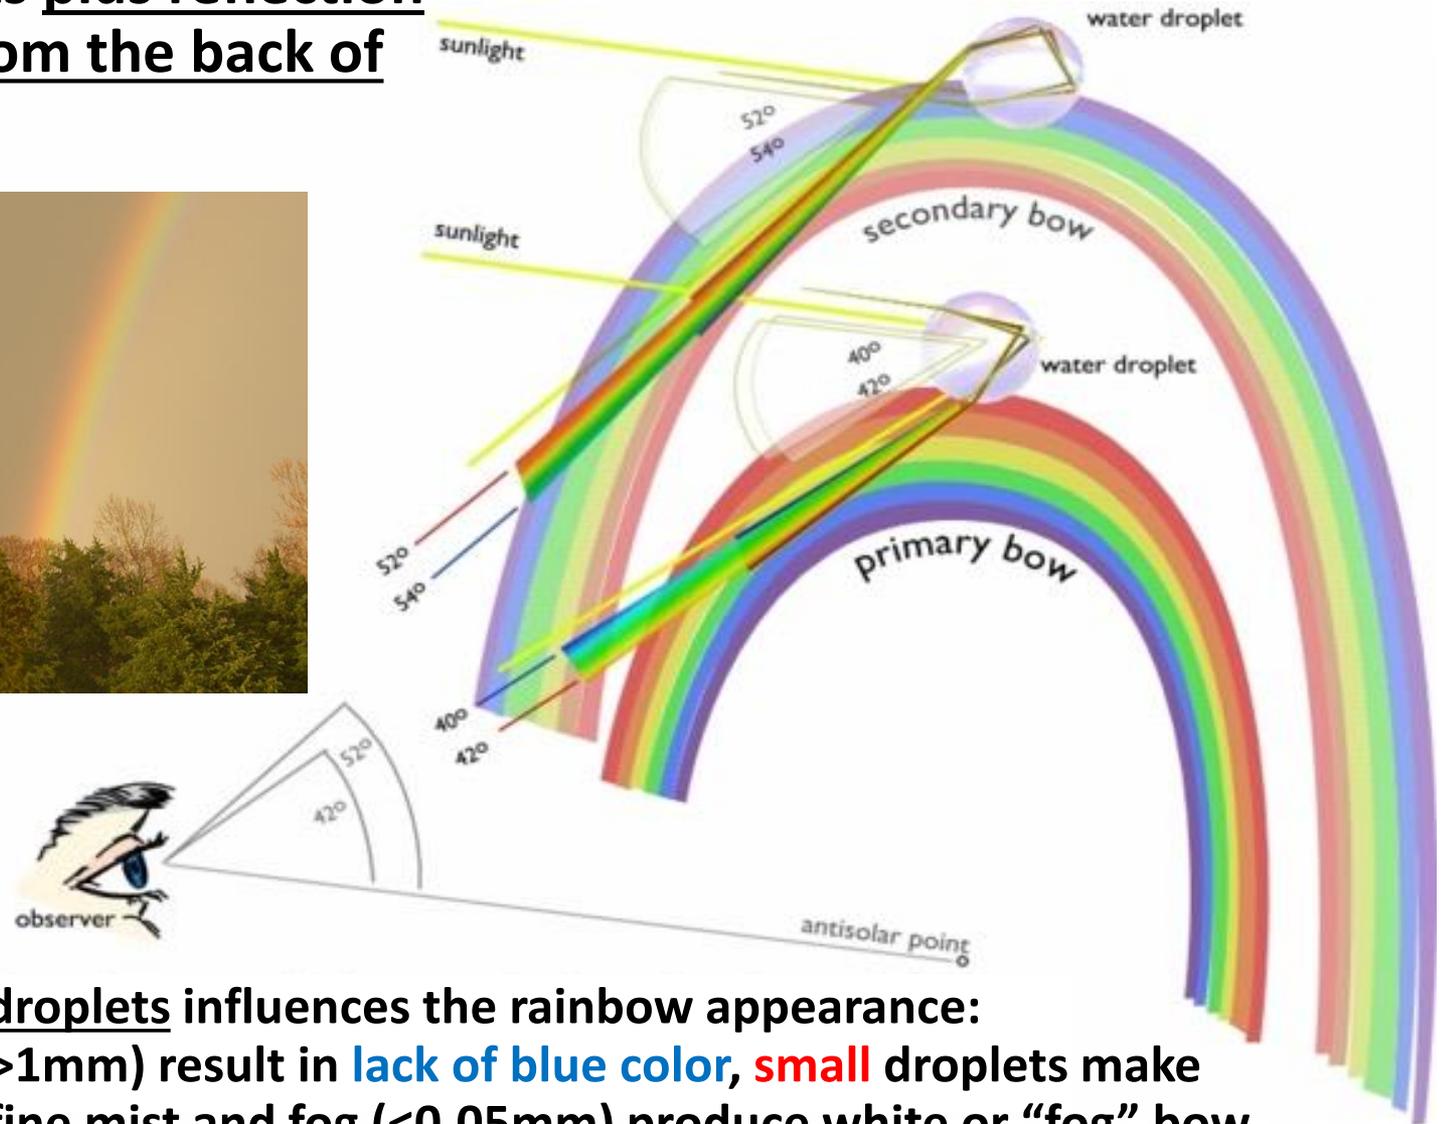

Glass prism

Water droplet

Rainbows result from refraction of sunlight in falling water droplets plus reflection of the light from the back of the droplet.

The size of the droplets influences the rainbow appearance: **large** droplets (>1mm) result in **lack of blue color**, **small** droplets make **red disappear**; fine mist and fog (<0.05mm) produce white or “fog” bow.

Can you see the **rainbow** when the Sun is overhead?

Can you see the full circle?

Think again 😊

All you
need to do
is
position
yourself
between
the Sun
and the
raincloud
and look
down!

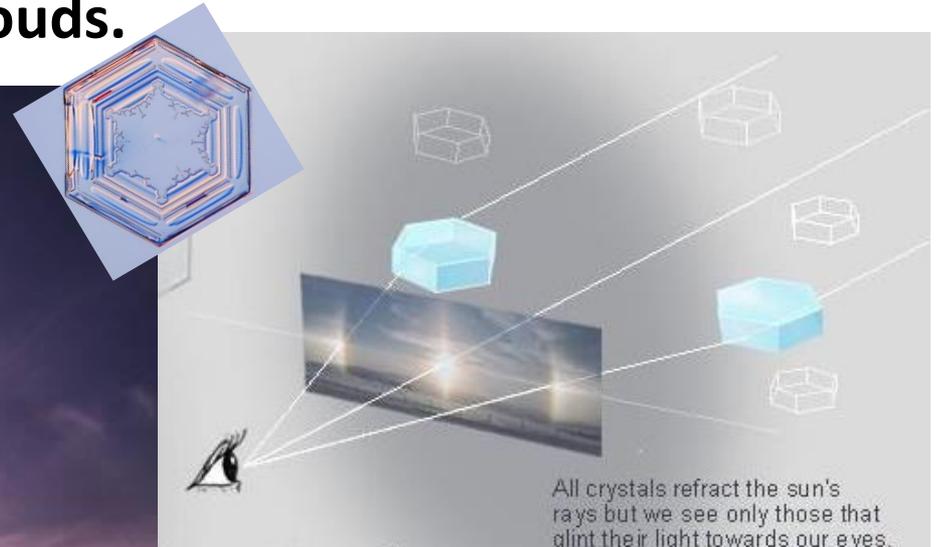

The Glory

What happens to light if we have **ice crystals in the air** instead of water droplets?

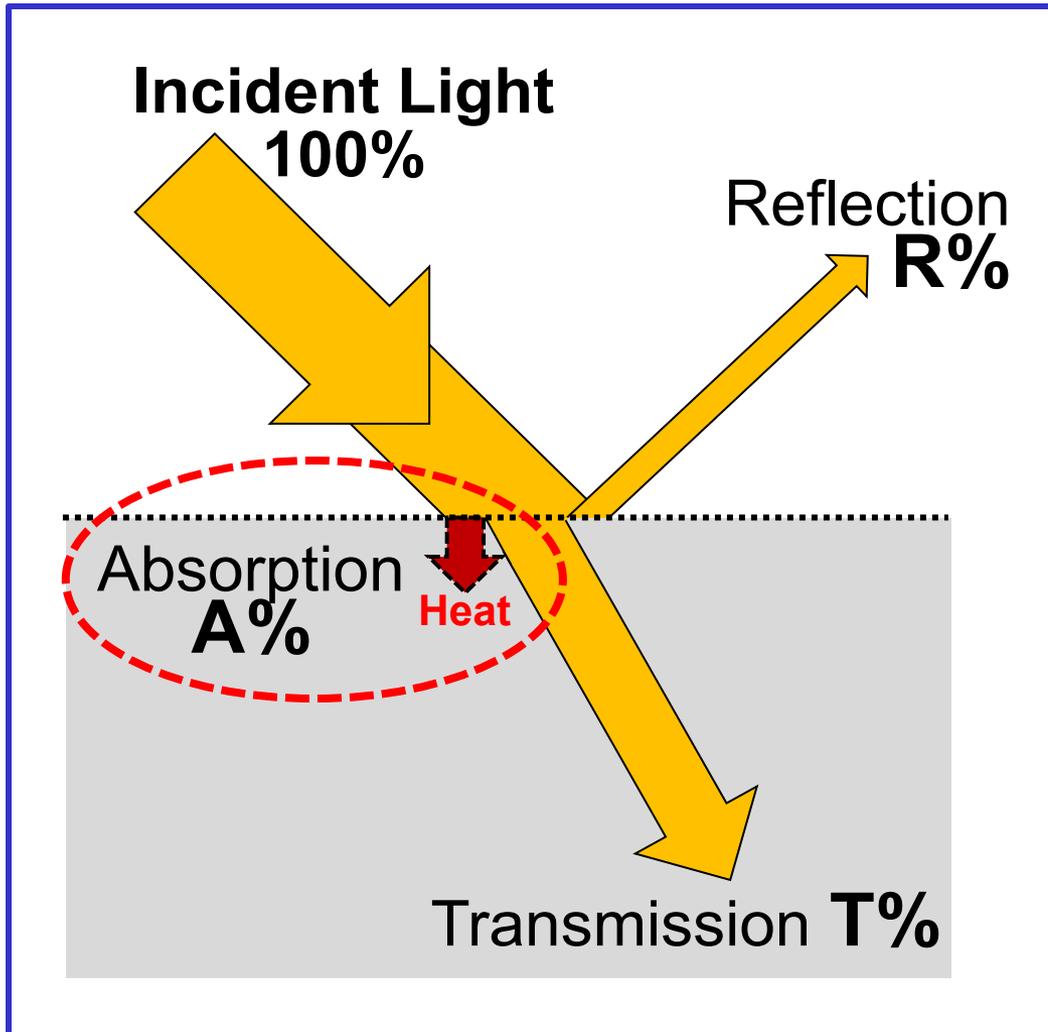

The Sun Halo and the Sun Dogs

formed by light refraction in **horizontally floating hexagonal plate ice crystals** high in the cirrus clouds.

The Sun Halo and the Sun Dogs occur world-wide but more common in cold climates.

Light Interaction with Non-Luminescent Matter

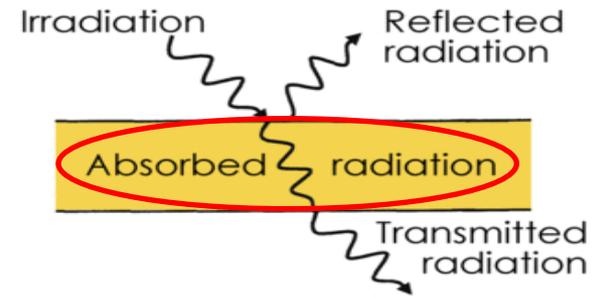

- Combination of transmission, reflection, and absorption:

$$T\% + R\% + A\% = 100\%$$

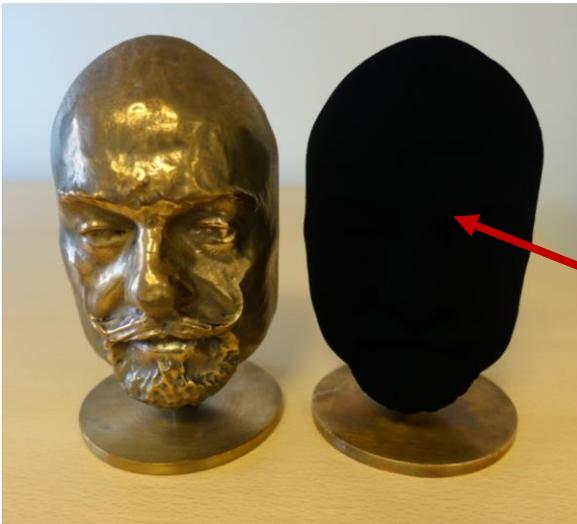

- No material is 100% transparent.
- No material is 100% absorbing either.

Absorption

disappearance of a light wave

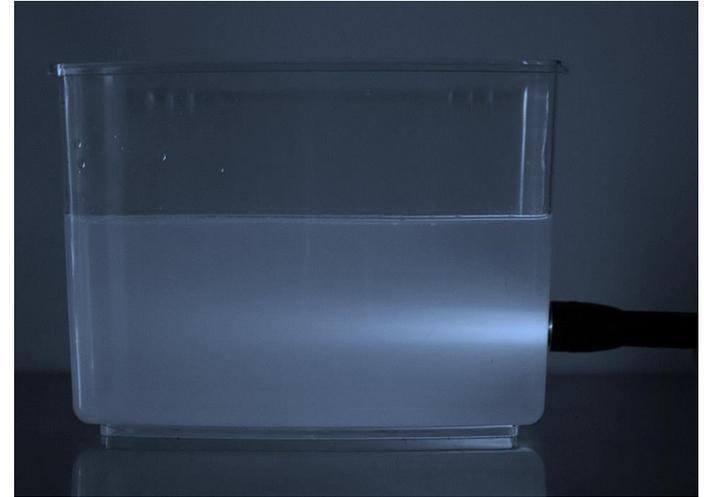

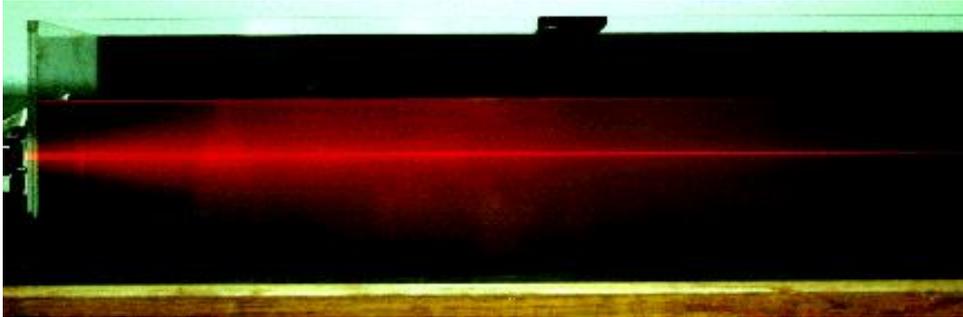

- The energy of a light wave is taken up by matter and in most cases converted into heat.
- **Dark opaque** objects absorb most of the incident light.

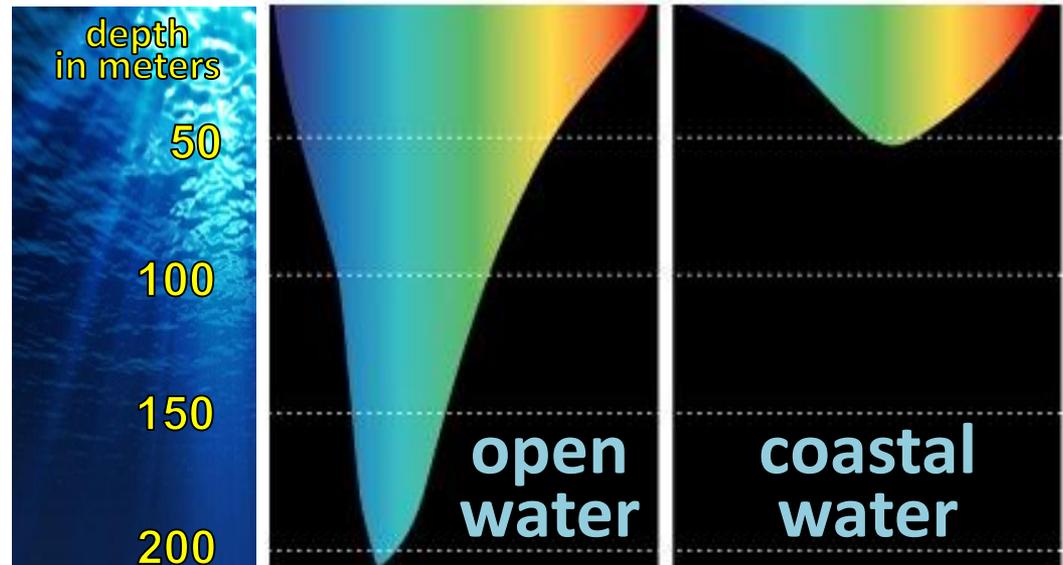

Vantablack – one of the darkest substances known, absorbing up to 99.965% of visible light!

Transparent and **translucent** objects always **absorb some part** of the incident light.

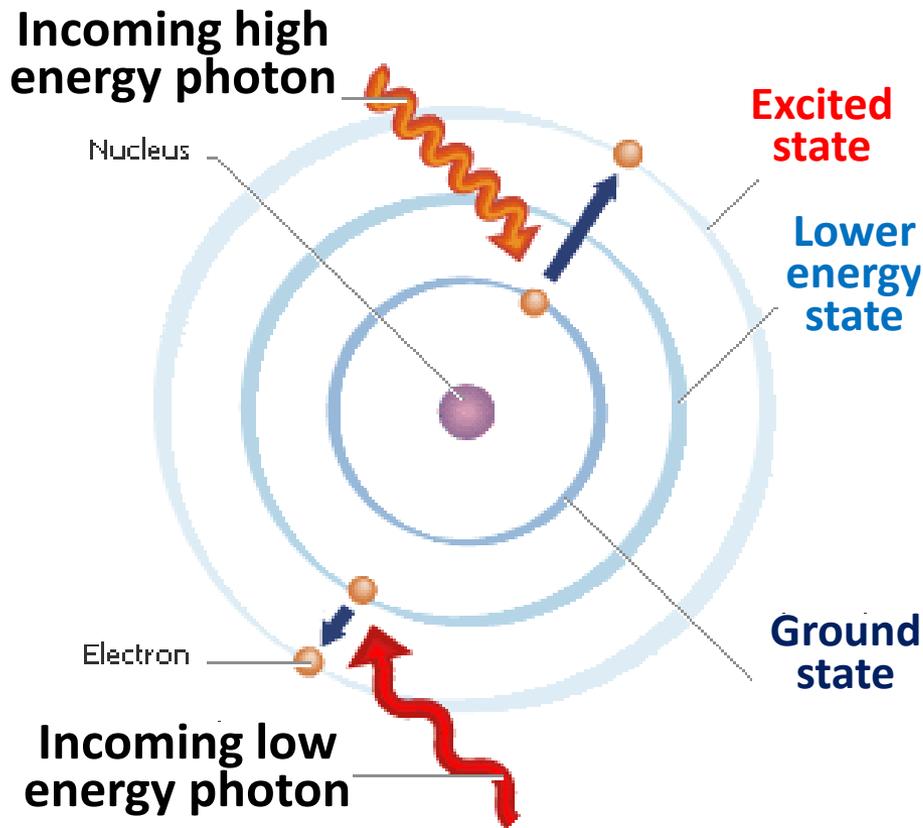

Absorption of Sunlight by Water

Absorption Spectrum

Absorption of light can happen when the **photon energy** (i.e. *frequency*) **matches** one of the **allowed transitions** between energy levels of a particular atom.

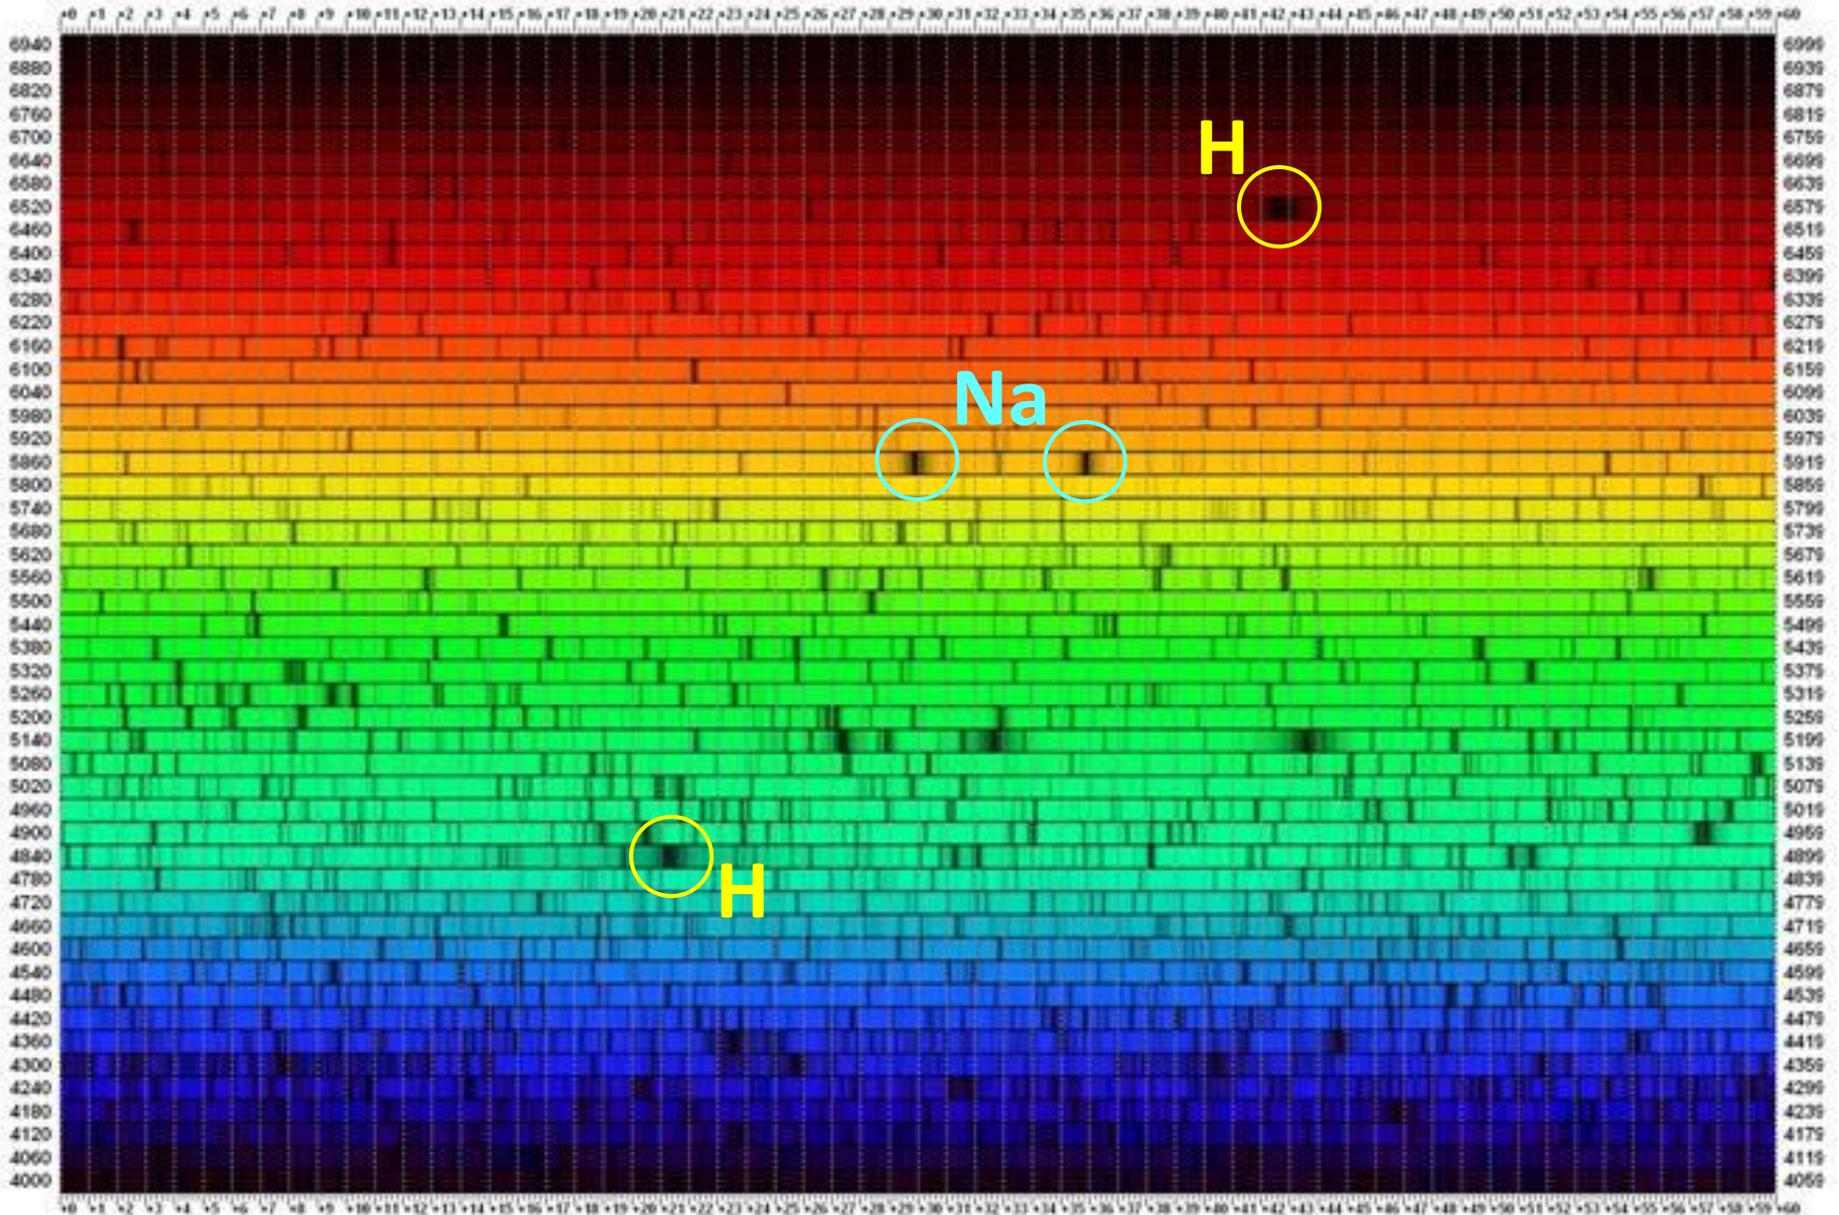

Example: Hydrogen

A **star** will create an absorption line spectrum because the continuous spectrum emitted by the dense, opaque gas that makes up most of the star passes through the cooler, transparent atmosphere of the star.

Absorption Spectrum of the Sun

Sunlight Filtered through Atmosphere

Absorption of sunlight by various **gas molecules** that are present in the Earth's atmosphere is seen as **absorption bands** in the Sun spectrum.
